Blois2011: 23rd Rencontres de Blois on Particle Physics and Cosmology 29 May - 3 June 2011

Motivation for top quark physics

- The top quark plays a special role in the electroweak sector and in QCD
 - Heaviest elementary particle known to date
 - Decays before hadronizing: unique window on "bare" quark
 - Top and W masses constrain the Higgs mass
- ➔ A tool for precise SM studies in the LHC energy regime
- Special role in various beyond SM extensions
 - New physics might be preferentially coupled to top
 - Non-standard couplings between top and gauge bosons
 - New particles can produce/decay to tops
- ➔ A sensitive probe to new physics
- In addition:
- ➔ A major source of background for many searches
- → A tool to understand/calibrate the detector, as all sub-detectors involved

CMS top quark measurements on 2010 data

CMS public results on the full 2010 pp dataset at $\sqrt{s} = 7 \text{ TeV}$: $\mathcal{L} = 35.9 \pm 1.4 \text{ pb}^{-1}$

- Top quark pair cross section measurements:
 - in dileptons (CMS-PAS TOP-11-002 (*))
 - in I+jets without b-tag (CMS-PAS TOP-10-002), with b-tag (CMS-PAS TOP-10-003)
 - combination of cross section measurements (CMS-PAS TOP-11-001)
- Single top quark cross section measurement (CMS-PAS TOP-10-008)
- Other top quark properties:
 - top mass in dileptons (CMS-PAS TOP-11-002 (*))
 - top pair invariant mass and searches for new physics (CMS-PAS TOP-10-007)
 - top pair charge asymmetry (CMS-PAS TOP-10-010)

(*) just submitted to JHEP, arXiv:1105:5661

σ (tī) in dileptons CMS-PAS TOP-11-002

• First measurement already with only 3 pb⁻¹! Phys. Lett. B695 (2011) 424

Simple *cut-and-count* experiment requiring
 2 OS isolated high-p_T leptons, Z veto, jets, E_T^{miss}

 Dedicated data-driven estimates for Drell-Yan and other background events with leptons

• 9 measurements:

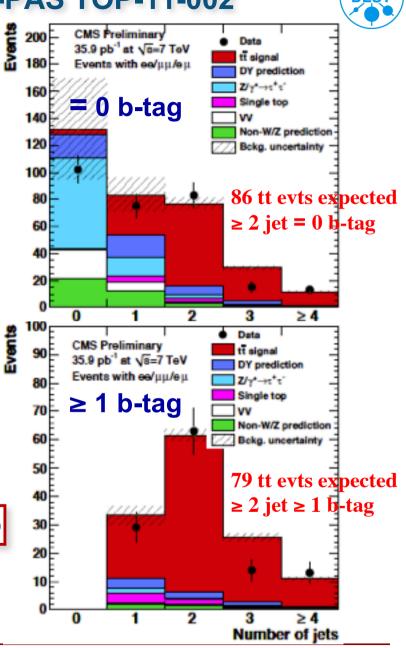

3 channels: ee, $\mu\mu$, μe $\begin{array}{c}
3 \text{ selections:} \\
\cdot N(jets) \ge 2, = 0 \text{ b-tag} \\
\cdot N(jets) \ge 2, \ge 1 \text{ b-tag} \\
\cdot N(jets) = 1, = 0 \text{-btag}
\end{array}$

Combined cross section:

14% precision

 $\sigma_{t\bar{t}} = 168 \pm 18(stat) \pm 14(syst) \pm 7(lumi) \text{ pb}$

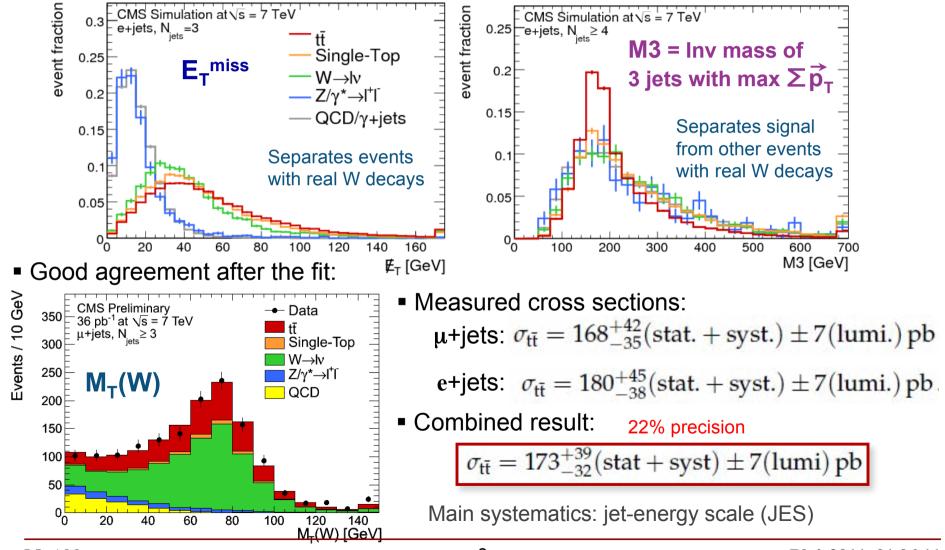

Major systematics: background modeling and b-tagging efficiency

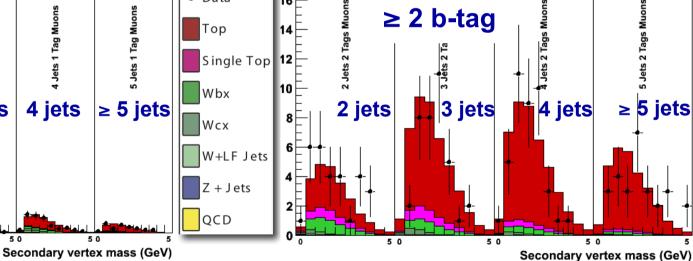

M. Aldaya

$\sim \sigma$ (tf) in I+jets without b-tag CMS-PAS TOP-10-002

- 1 isolated high- $p_T \mu/e$, veto on additional leptons, \geq 3 jets (no E_T^{miss} requirement)
- Simultaneous binned likelihood fit to E_T^{miss} with 3 jets and M3 with \geq 4 jets

0^L

≥ 2 b-tag

Main systematics, determined from the fit, due to JES, Q²-scale, b-tag efficiency

5.0

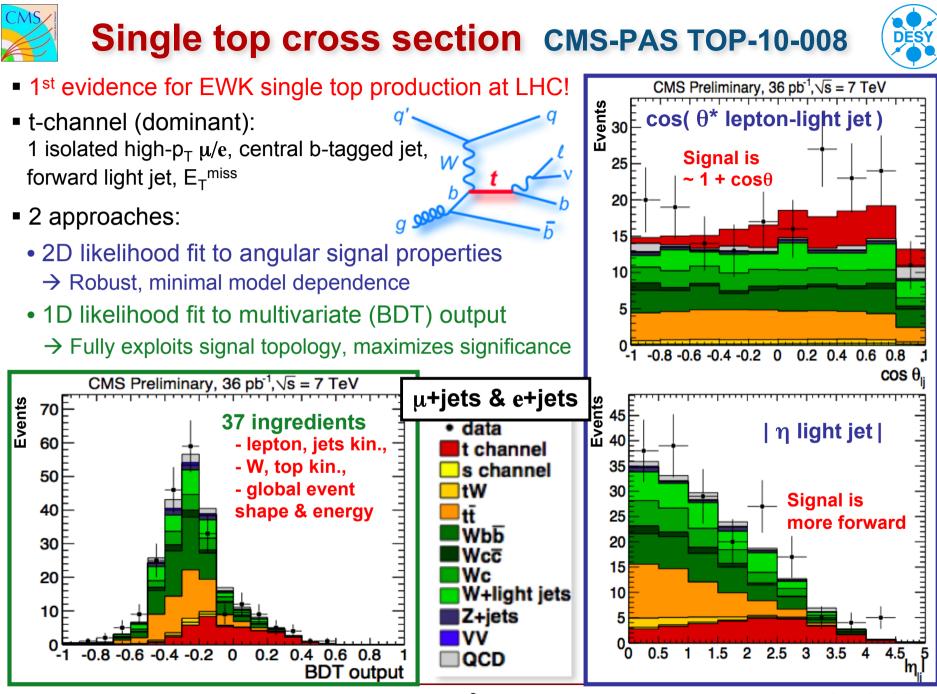

- Binned likelihood fit to secondary vertex (SV) mass \rightarrow separates light from heavy flavour
- Measurement in 9 different jet & b-tag multiplicities

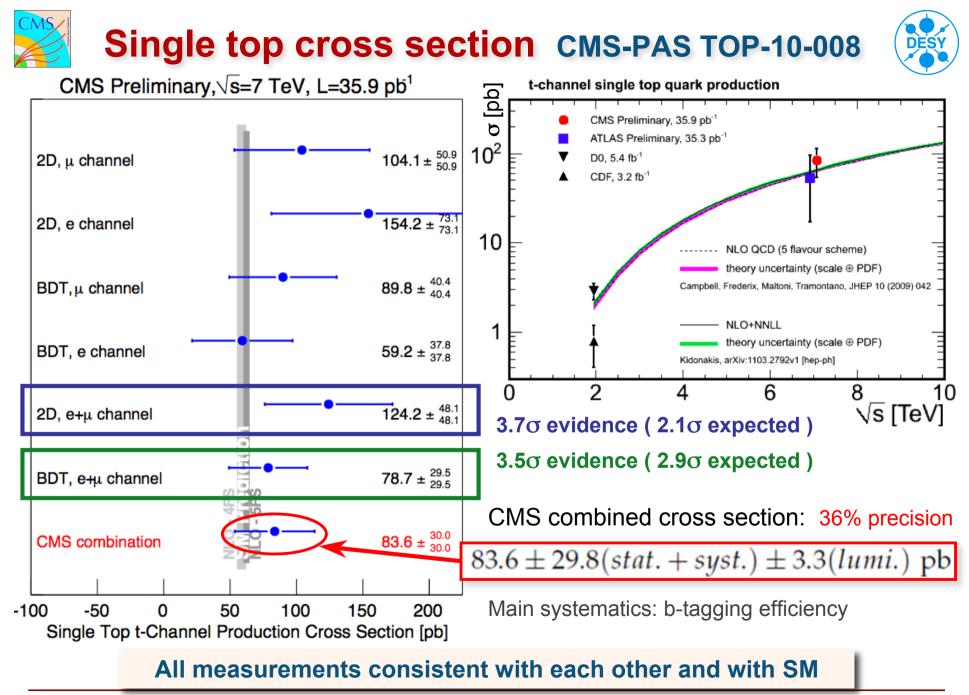

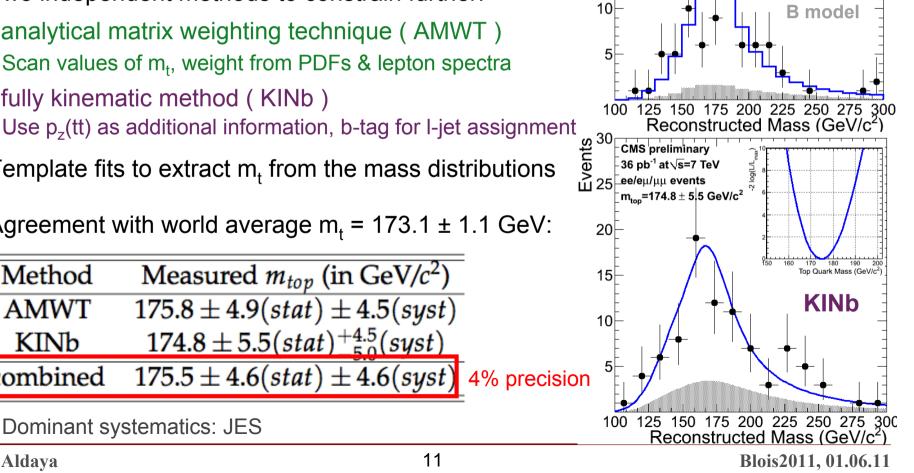

M. Aldaya

Blois2011, 01.06.11

imposing p_T conservation, $m_{top} = m_{antitop}$, M_W constraint

 \rightarrow final state reconstruction still under-constrained after

- Two independent methods to constrain further:
 - analytical matrix weighting technique (AMWT) Scan values of m_t, weight from PDFs & lepton spectra
 - fully kinematic method (KINb) Use $p_z(tt)$ as additional information, b-tag for l-jet assignment
- Template fits to extract m_t from the mass distributions
- Agreement with world average $m_t = 173.1 \pm 1.1$ GeV:

Top Quark Mass (GeV/c2)

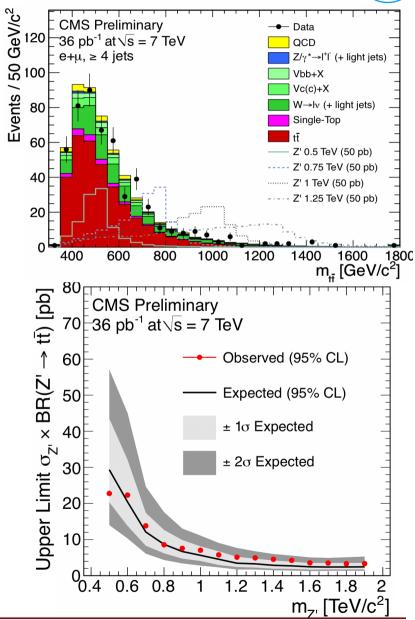

S+B model

 Search for heavy narrow resonances decaying into top pairs with e/μ+jets in the final state

 \rightarrow can modify the m_{tt} spectrum from SM predictions

- Energetic & isolated e/µ in an energetic hadronic environment with 2 b-jets
- Reconstruct m_{tt} using a kinematic fit
 - Separate in different lepton flavours and jet & b-tag multiplicities (8 categories)
 - For all relevant processes, use data-driven & MC-based templates
- Likelihood template fit to m_{tt}
- No significant signal observed
 - Limits set for narrow Z'-like particle production at the 95% C.L.
- Already competitive with Tevatron, particularly at higher masses

Top pair angular production asymmetries are a possible indicator of BSM top production interfering with SM production **Tevatron**

- Tevatron: proton-antiproton collider
 - Valence (anti)quarks from certain direction
 - → Forward-backward asymmetry

Reported a deviation from SM predicted $A_{FB} \sim 5\%$

- LHC: proton-proton collider
 - gg symmetric \rightarrow SM asymmetries more diluted
 - No valence antiquarks, quarks have higher x on average

 \rightarrow Asymmetry in $|\eta_{top}|$ - $|\eta_{antitop}|$ =N :

- SM prediction: A_C = 0.0130 ± 0.0011
- CMS measurement (unfolded):

 $A_C = 0.060 \pm 0.134 (\text{stat.}) \pm 0.026 (\text{syst.})$

Competitive with Tevatron with $\sim 1 \text{ fb}^{-1}$ of data

First measurement in top pair production in pp !

M. Aldaya

 $N^{+} - N^{-}$

Summary & outlook

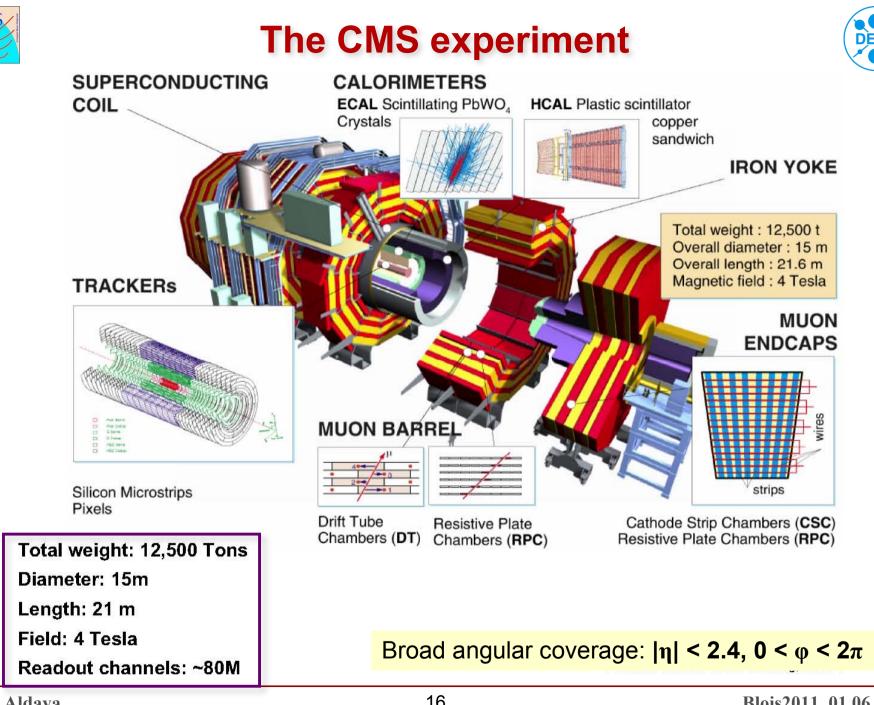

- In less than 1 year of operation at 7 TeV, CMS has produced many interesting results in the top quark sector with 36 pb⁻¹ of collected data:
 - Top-pair cross section in dilepton and lepton+jets channels (12% precision)
 - Single top cross section (36% precision)
 - Top mass in dileptons (4% precision)
 - Top-pair invariant mass -> limits on Z'-like particle production
 - Charge asymmetry
- More results expected soon:
 - Top mass in lepton+jets
 - Additional decay channels (all-hadronic, with taus)
 - Differential cross sections
 - More top-pair and single top properties
- So far, good agreement with SM predictions, but 2011 data already pouring in

 \ldots this is only the beginning \ldots

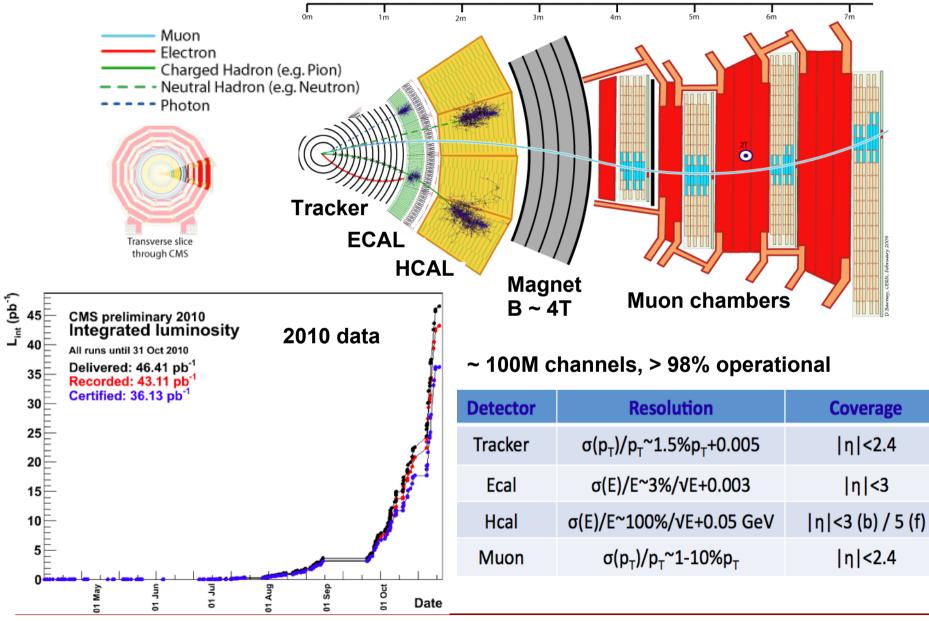

Additional information

The CMS experiment

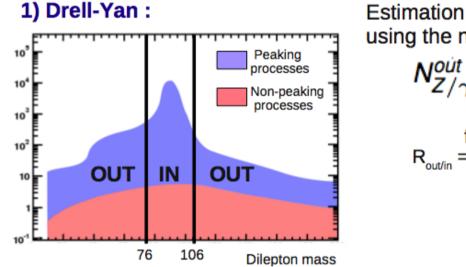

More info: Bckg estimation in dileptons

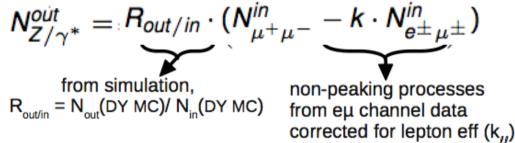

Background estimation from simulation:

single top (tW), semileptonic ttbar, diboson, Z/ $\gamma^* \rightarrow \tau + \tau$ -

Background estimation from data:

Estimation of the contribution outside the Z-veto region using the number of events inside the Z-veto region

2) Non W/Z decays lepton ("fakes") : QCD multijet, W+jets

Estimation of the contribution of fake leptons, $N^{\text{Tight}}_{\text{QCD}}$, using the number of events in a sample with loose identification requirement, $N^{\text{Loose}}_{\text{QCD}}$

$$N_{QCD}^{Tight} = R_{TL} \cdot N_{QCD}^{Loose}$$

R_{TL} = Probability that a loose lepton passes the tight selection. Determined from a multijet sample

Drell-Yan contribution

Non-W/Z contribution

Systematics

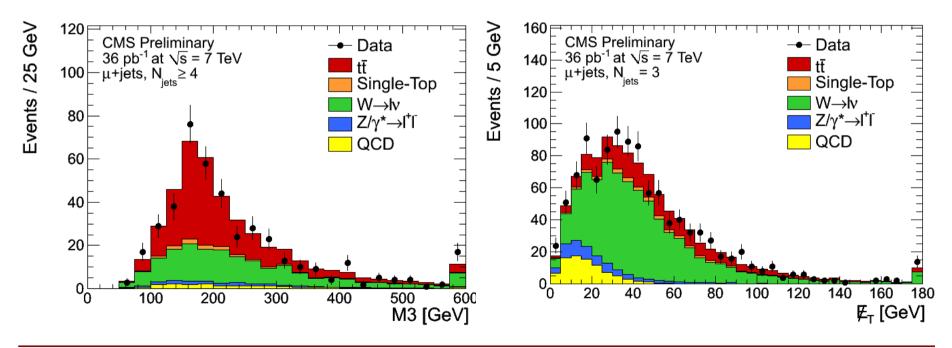

Table 3: Summary of systematic uncertainties relative to the rate of selected signal events estimated for the full signal selection. All values are in per cent. Systematic uncertainties on the lepton selection are treated separately for e^+e^- and $\mu^+\mu^-$ final states. Except for the lepton selection, values for all modes of a single source are treated as 100% correlated: the negative sign denotes anti-correlation. Different sources are treated as uncorrelated.

Fully Kinematic Method (KINb)

- Top quark reconstruction:
 - Solve equations of tt system many times per event
 - Scan kinematic phase space: vary $p_T(jet)$, $E_t^{miss} \& p_z(tt)$ independently according to resolution
 - Accept solutions with lowest m(tt) if $|m_{top} m_{antitop}| < 3 \text{ GeV}$
 - Choose the I-jet combination with largest number of solutions
 - m_{KIN} = outcome of gaussian fit around most probable value (± 50 GeV)

• Top mass determination:

- \bullet Unbinned likelihood fit to $m_{\rm KIN}$
- Free parameters: $m_{top},\,N_{sig,}\,N_{bg}$
- Background templates from simulation (shapes fixed); signal template (gaussian + landau) from fit to simulated signal sample

Analytical Matrix Weighting Technique (AMWT)

- Top quark reconstruction:
 - Solve equations of tt system many times per event
 - 8 solutions per event (4 for each of the 2 lepton-jet combination)
 - Scan m_{top} within [100 GeV, 300 GeV] in steps of 1 GeV
 - Assign a weight to each solution according to CTEQ6.1 PDF and the kinematics of the decay:

$$W = f(x)f(\overline{x})p(E^* \mid m_{top})p(\overline{E}^* \mid m_{top})$$

f(x) = PDF (summed over u, d, g)

p($E^*|m_{top}$) = probability of finding the lepton with energy E in the top rest frame by given m_{top}

- Sum weights of all solutions for a given m_{top} and average for different p_T (jet) within resolution
- m_{AMWT} = m_{top} with maximum average weight
- Top mass determination:
 - Calculate likelihood for different m_{top}
 - All templates from simulation except Z+jets background, which is taken from data in Z-mass window (fixed)

Systematics

Table 2: Summary of the systematic uncertainties (in GeV/ c^2) in the measurement of m_{top} , together with their correlations and combined values.

| Source | KINb | AMWT | Correlation factor | Combination |
|----------------------------|-----------|------|--------------------|-------------|
| jet energy scale | +3.1/-3.7 | 3.0 | 1 | 3.1 |
| <i>b</i> -jet energy scale | +2.2/-2.5 | 2.5 | 1 | 2.5 |
| Underlying event | 1.2 | 1.5 | 1 | 1.3 |
| Pileup | 0.9 | 1.1 | 1 | 1.0 |
| Jet-parton matching | 0.7 | 0.7 | 1 | 0.7 |
| Factorization scale | 0.7 | 0.6 | 1 | 0.6 |
| Fit calibration | 0.5 | 0.1 | 0 | 0.2 |
| MC generator | 0.9 | 0.2 | 1 | 0.5 |
| Parton density functions | 0.4 | 0.6 | 1 | 0.5 |
| b-tagging | 0.3 | 0.5 | 1 | 0.4 |

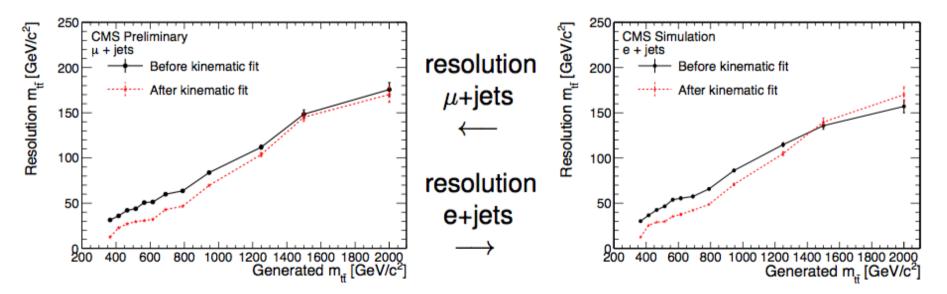

More info: top pair invariant mass

Reconstruction of m_{tt} done in 3 steps:

- Reconstruct leptonic W: $E_T^{miss} = p_T(v)$, $p_z(v)$ unmeasured
 - Impose W mass constraint: $m_{Iv} = m_W \rightarrow 2$ solutions for $p_z(v)$
 - If both real, keep both; if imaginary, modify E_T^{miss} within resolution to give real solution
- Association of jets to hadronic W decay and to the 2 b quarks by χ^2 minimization
 - 5 variables used: m_t^{lep} , m_t^{had} , $p_T(tt)$, H_T fraction (= sum of $E_T^{selected jets}$ / sum of $E_T^{all jets}$)
- Kinematic fit to improve resolution

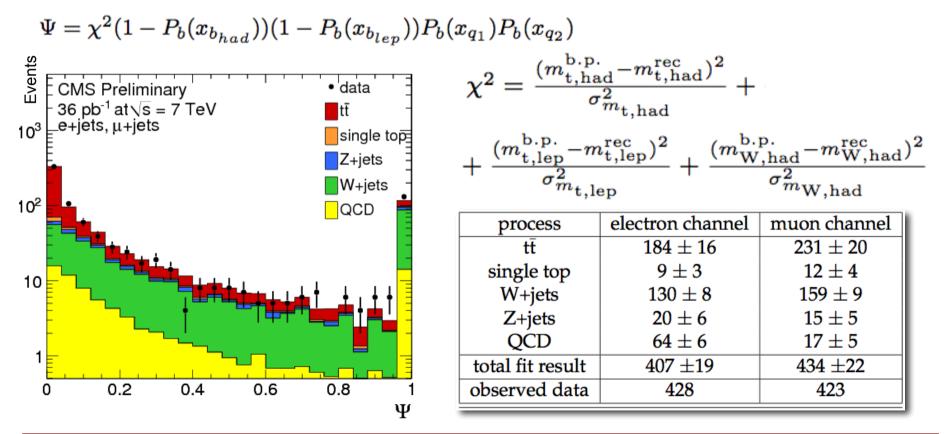

More info: Charge asymmetry

Reconstruction of ttbar final state: (following event selection from TOP-10-002)

- Reconstruct leptonic W: $E_T^{miss} = p_T(v)$, $p_z(v)$ unmeasured
 - Impose W mass constraint: $m_{Iv} = m_W \rightarrow 2$ solutions for $p_z(v)$; if imaginary, take Re

 \bullet For each possible 4-jet combination, determine Ψ and take the hypothesis with the smallest value of Ψ :

More info: Charge asymmetry

Unfolding: correct the measured $|\eta_{top}| - |\eta_{antitop}|$ from several effects:

- Background contributions:
 - use orthogonal samples from diagonalized covariance matrix and subtract them from the measured spectrum: $A_c^{rec} = 0.018 \pm 0.034$ (stat) $\rightarrow A_c^{rec} = 0.035 \pm 0.070$ (stat)
- Smearing and selection effects:
 - Define matrix $\mathbf{y} = A \mathbf{x}$, where $\mathbf{x} =$ true spectrum ; $\mathbf{y} =$ measured distribution
 - A is taken from simulation, measured scale factors from overall selection eff accounted for
 - Equation solved by a generalized inversion process of matrix A
